METHOD FOR TREATMENT OF A FLUID QUANTITY INCLUDING CHEMICAL REACTING  
MEANS SUCH AS COMBUSTIBLE MATERIALS AND A CATALYTIC DEVICE

5 **Background of the invention**

The invention relates to a method for treatment of a fluid quantity including chemical reacting means such as combustible materials and a catalytic device according to the preamble of claims 17 and 70.

10

Most of the known catalysts for cleaning of exhaust gasses from internal combustion engines contain no internal heat exchange. This means that the maximum temperature in the catalyst depends on the inlet temperature in said catalyst. If the unburned gas components by combustion e.g. can increase the temperature in the catalyst by 200°C an inlet temperature of 300°C will result in a maximum temperature of 500°C, an inlet temperature of 400°C will result in a maximum temperature of 600°C, etc. However, an inlet temperature of 200°C does not necessarily result in a maximum temperature of 400°C as the temperature at that time is too low for the reactions to take place and the catalyst will be wholly or partly inactive.

However, catalysts with internal heat exchange have been suggested in previous patent documents such as US patent no. 6,207,116. The US patent discloses a catalyst comprising a zig-zag folded metal plate coated with catalytic material. The folded plate is positioned in a container. The container comprises an inlet and outlet for gas in which the gas enters the container through the inlet. Hereafter the gas is directed along one side of the metal plate and subsequently returned along the other side before leaving the catalyst through the outlet. A heat exchange may take place from one side to the other side of the metal plate during the flow of the gas e.g. the returning gas heats the gas which has just entered the catalyst. However, the heat exchange is not enough to achieve satisfying and stable temperature conditions

inside the catalyst in the heating-up periods and thus, the catalyst comprises temperature regulating means in opposite ends of the container. The means may for example be electric coils connected to an electric power supply positioned outside the catalyst with the disadvantage of the electric energy use. Further, the connection for the electric coils is a significant disadvantage due to the price, complexity and vulnerability of the coils and the connections.

An object of the invention is to establish a catalytic device without the above-mentioned disadvantage, and especially a catalytic device with preferred and stable 10 temperature conditions but without the use of externally supplied energy for temperature regulation means.

A further object of the invention is to establish a self-regulating catalytic device in order to obtain a very specific and constant maximum temperature.

15 An even further object of the invention is to establish a catalytic device with improved initial self-regulating capabilities.

## 20 The invention

The invention relates to a catalytic device in which said device further comprises means for controlling the temperature in one or more of said passage sections.

25 Hereby are disadvantages in catalysts of the prior art avoided.

In an aspect of the invention, said means for controlling the temperature includes positioning of said passage sections in order to form at least one internal heat exchanger with mutual heat exchange between the sections.

30

In an aspect of the invention, said catalytic device comprises at least three passage sections.

In an aspect of the invention, said catalytic device comprises four passage sections.

5

In an aspect of the invention, said fourth passage section is the last outlet passage section surrounding the previous passage sections.

In an aspect of the invention, said device comprises a container including said inlet,  
10 said passage sections and said outlet.

In an aspect of the invention, at least one turning chamber between two of said passage sections comprises a connection to the exhaust pipe section controlled by at least one valve.

15

In an aspect of the invention, each of said at least one valve comprises a closing member and temperature dependent connection means connecting said closing member and an anchoring point.

20 In an aspect of the invention, said temperature dependent connection means is a spring made in bimetal or a similar temperature dependent material.

In an aspect of the invention, said temperature dependent connection means partly or totally is positioned in the outlet pipe such as the outlet passage sections, valve pipe  
25 section, exhaust pipe section or the outlet pipe section.

In an aspect of the invention, said outlet pipe comprises a valve pipe section including at least one valve, an outlet pipe section connected to the outlet passage section, in which both pipe sections are connected to an exhaust pipe section.

30

In an aspect of the invention, said temperature dependent connection means partly or totally is positioned in proximity of the connection between said pipe sections or in the exhaust pipe section.

- 5 In an aspect of the invention, said device includes temperature-measuring means measuring the temperature inside one or more of said passage sections, one or more turning chambers and/or said inlet.

- In an aspect of the invention, valve control means (34) controls the position of said at  
10 least one valve on the basis of temperature values from said temperature-measuring  
means.

- The invention also relates to a method for treatment of a fluid quantity including  
chemical reacting means such as combustible materials above a certain minimum  
15 quantity in a catalytic device, said method comprises the steps of

- entering said fluid quantity into the catalytic device through an inlet,  
directing said fluid quantity through at least three passage sections of said catalytic  
20 device in which at least one section includes catalytic material of one or more kinds  
in which the catalytic material reacts with and/or enhances the reactions of said  
combustible materials,  
heating or cooling said fluid quantity in said at least three passage sections by  
25 internal heat exchange in said catalytic device between said sections, and  
emitting the treated fluid quantity from the catalytic device through an outlet.

Hereby are disadvantages in catalysts of the prior art avoided.

Further, by the invention is it obtained that the maximum temperature in the catalytic device is always nearly constant whatever the inlet temperature, but assuming a certain minimum inlet temperature and minimum amount of combustible material. Hereby, the catalytic device can be designed to work at a very specific temperature.

- 5 as an example at 600°C, by which it is possible, partly to ensure a better and safer burnout of the unburned components, and partly to save expenses for catalytic materials as a catalyst that is designed for a certain temperature can be made from materials that are less expensive than the materials for a catalyst that has to work over a large temperature range.

10

The method can be used for cleaning of any fluid such as every gas, air or liquid quantity comprising chemical reacting means such as combustible materials above a certain minimum quantity.

15

It shall be emphasised that the term "catalytic material" should be understood as material that reacts with the combustible materials and/or enhances the reaction of the combustible materials e.g. speeds up the process without reacting with the combustible materials as such.

20

In an aspect of the invention, a main reaction passage section heat exchanges with a main heat transfer passage section, and where the main reaction passage section heat exchanges with one or more preceding inlet passage sections and/or one or more succeeding outlet passage sections. Hereby it is possible to heat up the whole catalytic device rather quickly.

25

In a further aspect of the invention, the fluid quantity is directed through the succeeding passage sections in counterflow. Hereby it is possible to achieve a high maximum temperature with a relatively low inlet temperature.

30

In another aspect of the invention, further combustible material is added directly or indirectly to the catalytic device. Hereby it is possible even with small amounts of

## 6

additional fuel to raise the temperature in order to make the catalytic device more stable and to save device material e.g. the device can be made smaller and still be effective.

- 5 The invention further relates to a catalytic device in which said container comprises at least three passage sections being mutually connected,

where at least one section of said passage sections includes catalytic material of one or more kinds, and

- 10 where the positioning of said passage sections forms at least one internal heat exchanger with mutual heat exchange between the sections.

- 15 The catalytic device can be used for cleaning of any fluid such as every gas, air or liquid quantity comprising chemical reacting means such as combustible materials above a certain minimum quantity. The invention will possibly also be of use within the fuel cell technology and in chemical industry where exothermal or endothermal reactions take place.

- 20 Further, the catalyst can be designed to work at a very specific temperature, by which it is possible, partly to ensure a better and safer burnout of the unburned components, and partly to save expenses for catalytic materials.

- In an aspect of the invention, said catalytic device comprises three passage sections.  
25 Hereby is achieved an advantageous relation between price and size and the efficiency of the device.

- 30 In a further aspect of the invention, said one or more inlet passage sections is positioned above, alongside or outside said main reaction passage section e.g. by surrounding said section. Hereby is achieved an advantageous preheating of the inlet fluid before entering the reaction passage section.

In another aspect of the invention, said one or more outlet passage sections is positioned above, alongside or outside said main reaction passage section e.g. by surrounding said section. Hereby it is possible to preheat the fluid in some of the  
5 main reaction passage section by the outlet passage section fluid.

In another aspect of the invention, said main reaction passage section is positioned above, alongside or outside said main heat transfer passage section e.g. by surrounding said section. Hereby it is possible to achieve a preferred and  
10 advantageous embodiment of the invention.

In another aspect of the invention, at least one of said at least three passage sections, such as said main heat transfer passage section, comprises one or more substantially parallel pipes.

15 In another aspect of the invention, said main heat transfer passage section is integrated as a number of pipes in said main reaction passage section. Hereby is achieved a very compact device with an enhanced heat exchange between the sections.

20 In another aspect of the invention, said number of pipes is between 20 and 5000 pipes and preferably between 50 and 1000 pipes. Hereby is achieved a preferred and enhanced heat exchange between the sections.

25 In another aspect of the invention, said pipes form symmetrical patterns such as triangular, quadrangular or similar patterns or random patterns. Hereby is achieved a preferred relation between heat exchange and flow resistance.

30 In another aspect of the invention, said pipes is surrounded by catalytic material deposited on one or more carrier means. By surrounding the pipes is achieved a

preferred and homogenised heat exchange from the section passage comprising carrier material to the pipes.

In another aspect of the invention, said pipes comprise a circular, an oval, a 5 triangular, a four-sided or any similar regular or irregular cross sectional shape. By the shape is achieved a preferred relation between the shape, flow resistance and production price.

In a further aspect of the invention, at least one of said three passage sections, such 10 as said main heat transfer passage section (5), comprises one or more lamellar plates.

In a further aspect of the invention, said one or more lamellar plates form non-circular canals e.g. with a cross sectional shape formed by triangles, four sided shapes, combinations hereof or similar shapes.

15 In a further aspect of the invention, indentations in the surface of said one or more lamellar plates form longitudinal or diagonal patterns.

In a further aspect of the invention, said catalytic material is deposited on one or 20 more carrier means in at least one of said at least three passage sections. Depositing the material on carrier means enhanced flexibility as the shape and surface of the carrier means may be designed to the relevant application e.g. in order to achieve large surface, low pressure drop, high heat transfer, small sized catalytic device or the like. Further, it is possible to fit the surface area and pressure drop through the 25 device for the application in question.

In a further aspect of the invention, said one or more carrier means are made in metal, ceramic, glass or other heat resistant materials as well as combinations of the mentioned materials. Hereby is established material that may tolerate the high 30 temperatures of the catalytic device in longer periods without sustaining cracks or

rupturing. Further, it is possible to find the exact best fit material for the application in question.

In a further aspect of the invention, said one or more carrier means include at least  
5 one shape such as spherical, cylindrical or quadrangular shapes as well as saddle,  
ring, regular or irregular shapes. Hereby it is possible to fit the surface area and  
pressure drop through the device for the application in question.

In a further aspect of the invention, said one or more carrier means include a number  
10 of regular or irregular balls in layers across one of said passage sections, each layer  
being positioned perpendicularly between two adjacent pipes, and each of said layers  
comprising 2 to 6 balls, such as 2 to 4 and preferably between 2 and 3. Hereby it is  
possible to achieve a low pressure drop through the device.

15 In a further aspect of the invention, said one or more carrier means include monoliths  
or fibres. Hereby it is possible to achieve a large surface without creating large  
pressure drops through the sections.

In a further aspect of the invention, said fibres, deposit with said catalytic material  
20 form a tangled bundle of fibres partly or totally filling one or more of said passage  
sections. Hereby it is possible to create price efficient catalytic material with a very  
large surface. Further, the material is easily filled into the section passage.

In a further aspect of the invention, said monoliths or fibres, deposit with said  
25 catalytic material form longitudinal monoliths or fibres inside one or more of said  
passage sections. Hereby it is possible to reduce the pressure drop through the device  
because of the orientation of the monoliths or fibres.

In an even further aspect of the invention, said main reaction passage section of said  
30 at least three passage sections comprises one or more kinds of said catalytic material  
deposit on said carrier means.

In an even further aspect of the invention, said one or more inlet and/or outlet passage sections of said at least three passage sections comprises one or more kinds of said catalytic material deposit on said carrier means.

5

In an even further aspect of the invention, one or more of said at least three passage sections comprise combined carrier means including wall flow filters, fibres, balls and/or monoliths e.g. 1/3 passage section as wall flow filters and the rest of the section as fibres, balls or monoliths.

10

In an even further aspect of the invention, said combined carrier means are positioned in continuation of each other through one or more of said at least three passages. Hereby it is possible to establish enhanced devices with the advantages of all the types of carrier means.

15

In an even further aspect of the invention, said catalytic material includes metal or metal alloys from the Platinum metal group such as Platinum (Pt), Palladium (Pd), Rhodium (Rh) or combinations hereof. Hereby it is possible to create catalytic devices with optimal cleaning abilities for fluids such as exhaust gases from internal combustion engines.

In an even further aspect of the invention, said catalytic material includes metal oxides such as Gold (Au), Platinum (Pt), Silver (Ag), Aluminium (Al), Lead (Pb), Zirconium (Zr), Copper (Cu), Cobalt (Co), Nickel (Ni), Iron (Fe), Cerium (Ce),  
25 Chrome (Cr), Tin (Sn), Manganese (Mn) and Rhodium (Rh) Oxides or combinations hereof. The use of metal oxides as catalytic material makes it possible to create more price efficient catalytic devices.

In an even further aspect of the invention, said catalytic material includes  
30 combinations of metal or metal alloys from the Platinum metal group and metal

oxides. Hereby it is possible to optimise the performance and characteristics of the catalytic material by using the advantages of both material types.

- In an even further aspect of the invention, said main reaction passage section heat exchanges with said main heat transfer passage section of said at least three passage sections.

In an even further aspect of the invention, said main reaction passage section heat exchanges with said main heat transfer passage section in counterflow.

- 10 In an even further aspect of the invention, said main reaction passage section heat exchanges with said one or more previous inlet and/or succeeding outlet passage sections.

- 15 In an even further aspect of the invention, said main reaction passage section heat exchanges with said one or more inlet passage sections in counterflow.

In an even further aspect of the invention, said main reaction passage section heat exchanges with said one or more outlet passage sections in concurrent flow.

- 20 In an even further aspect of the invention, said device comprises at least one layer of insulation between said at least three passage sections. Hereby, it is possible to reduce or control the heat exchange between the passage sections.

- 25 In an even further aspect of the invention, said at least one layer of insulation is positioned between said main reaction passage section and said one or more inlet passage sections. Hereby, it is possible to reduce or control the heat exchange between the fluid flows in preferred passage sections.

- 30 In an even further aspect of the invention, the cross-sectional area of said main reaction passage section is between 0.5 and 100 times, such as between 10 and 25

times, preferably about 20 times, the cross-sectional area of said main heat transfer passage section and/or said inlet or outlet passage sections are between 0.5 and 100 times, the cross-sectional area of said main heat transfer passage section. Hereby is achieved an advantageous relation between the passage sections.

5

It shall be emphasised that the cross sectional areas are all the flow areas of the sections e.g. the areas of all the pipes in the main heat transfer passage sections.

In an even further aspect of the invention, the cross-sectional area of the main heat  
10 transfer passage section is between 0.5 and 10 times, such as 1.5 to 2.5 times, preferably about 2 times, the cross-sectional area of the inlet of the catalytic device, said inlet pipe being the exhaust pipe for the connected internal combustion engine. Hereby is achieved an advantageous embodiment of the invention.

15 In an even further aspect of the invention, at least one of said passage sections comprises one or more wall flow filters with numerous porous walls allowing fluid quantity to penetrate through the walls. Hereby is achieved an advantageous embodiment of the invention.

20 In an even further aspect of the invention, further combustion material is added to the device, e.g. through a fuel line to the fuel tank and the fuel supplying means, or through adding further combustion material to the fluid quantity. Hereby it is possible to control and optimize the process of the catalytic device e.g. by raising the temperature inside the device.

25

The different aspects of the invention make the catalytic device and especially the heat exchange more efficient the slower the chemical reactions in the catalyst are, and vice versa. Therefore, the catalytic device will, by itself, set itself for the right temperature so that all reactions precisely can be completed in the catalytic device.

15

**Detailed description**

Fig. 1 illustrates schematically an application including a catalytic device according to the invention.

20

The application includes combustion and fuel supplying means S1, S2 in which the fuel supplying means S1 supplies a combustible fuel to the combustion means S2. After the combustion at the combustion means, any exhaust gas of the combustion is directed to a catalytic device with internal heat exchange. The catalytic device with 25 internal heat exchange may also be named a recuperative catalytic device.

The catalytic device can among other things be used for vehicles with an internal combustion engine such as an engine fuelled by petrol, diesel, natural gas, bottled gas or any similar fuels. The combustion engine S2 is supplied with fuel from a fuel 30 tank or container by the help of a fuel pump S1 pumping the fuel.

Further uses of the catalytic device may be in connection with stationary engines such as combustion engines at power plants, e.g. combined heat and power plants, using petrol, diesel, natural or bottled gas or any similar fuels.

- 5 The exhaust gases of the combustion means include a certain amount of unburned gas components that can be converted in the catalytic device. The catalytic device can be designed to convert unburned hydrocarbon (UHC), carbon monoxide (CO), nitric oxides (NO<sub>x</sub>) and/or particles from combustion engines.
- 10 A further use of the device may be in the chemical industry. Whenever an exothermal process needs external heating before the process to make the process effective the device according to the invention may be used to save energy in this process, e.g. in fuel conversion processes.
- 15 Another use of the device may be in connection with fuel cell technology. At any exothermal process in the fuel cells or in connection with the fuel cells in which external heating is needed before the process the device according to the invention may be used for implicit internal control of the temperature.
- 20 Fig. 2 illustrates a longitudinal section of a catalyst 1. From the inlet 2 the gases pass into the first passage 3 with catalytic materials 4 (illustrated as hatched areas) in which the gases react at the same time as they heat exchange with the last passage 5 through the exchange surface 6 before the outlet chamber 7 and the outlet 8.
- 25 The inlet and/or the outlet may be connected to one or more further passage sections in order to establish at least three passage sections.  
The maximum temperature may be obtained in the turning chamber 9 in which the gases turn form the first passage section 3 to the second passage section 5. The temperature in the turning chamber 9 will be the temperature of the gases when these have completed reacting in the passage section 3. If the temperature inside the
- 30

passage section 3 is high, the gases will react in the beginning of this passage and the heat exchange between the gases in the second passage section 5 and in the first passage section 3 will be at a minimum.

- 5 If the temperature inside the first passage section 3 is low, the gases will react near the outlet of this passage section. The temperature difference between the gases in the second passage section 5 and in the passage section 3 will thus be big throughout the entire length of the heat exchanger and the heat exchange will be at a maximum by which the gases in the passage section 3 is heated by the gases in the passage 10 section 5 in order to react at the end of the passage section 3.

The walls that are part of the passage sections and the heat exchanger are preferably made in materials with good heat conductivity such as metals or metal alloys e.g. steel or aluminium.

- 15 Fig. 3 illustrates a preferred embodiment of the catalytic device according to the invention where the gas from the inlet pipe 2 enters the container c comprising at least three passage sections forming a heat exchanger h. At the entrance, the gas meets the inlet chamber 10 after which it is distributed in the inlet passage section 11 in the catalytic device 1. If the conditions for reaction are met, the first reactions will start and maybe be finished in this passage section 11 after which the rest of the passage sections 3 and 5, the main reaction and the main heat transfer passage sections, will obtain the same maximum temperature. To the extent that the temperature inside the inlet chamber 10 is lower, the reaction of the gases will move 20 to the main reaction passage section 3, and the rest of the catalytic device works hereafter as described above concerning fig. 2.

- 25 The passage section is illustrated as four pipe positioned above each other. However, it shall be emphasised that the number of pipes usually are between 20 and 5000 and 30 preferably between 50 and 1000 pipes. The pipes may be positioned randomly or in one or more patterns as will be further explained below e.g. in connection with fig. 4.

- The gas is guided through the catalytic device by the at least three passage sections that have a mutual internal heat exchange. In the second passage, the main reaction passage section, there are catalytic materials 4 (illustrated with similar hatched areas as fig. 2) of one or more kinds, in which the gas can react, and in which the gases heat exchange with the succeeding main heat transfer passage section. Hereby is obtained an internal heat exchange placed in the catalytic device. This means that the catalytic device and the heat exchanger h are fully integrated.
- 5      10      The outlet temperature of the gas may, according to the invention, still be the same as in a conventional catalyst. However, the internal heat exchange results in the temperature reaching a maximum preferably in the turning chamber between main reaction passage section and the main heat transfer passage section. The specific design makes the heat exchanger more efficient the slower the chemical reactions in
- 15      15      the catalytic material are, and vice versa. Hereby, a nearly constant temperature is ensured and especially in the turning chamber between main reaction passage section and the main heat transfer passage section. The constant temperature may be higher than the outlet temperature for the catalytic device.
- 20      20      If the chemical reactions are fast, the heat exchanger will almost be inactive as all reactions are completed in the first part of the catalytic material in the main reaction passage section.
- 25      25      If the chemical reactions are slow, the heat exchanger will especially become active as the chemical reactions will take place in the last part of the catalytic material in the main reaction passage section.
- 30      30      The catalytic device will, by itself, set itself for the right temperature so that all reactions precisely can be completed in the catalytic device, and the temperature will not increase further. The catalytic device is therefore self-regulating with an almost

constant maximum temperature in which the constant maximum temperature usually will occur in the turning chamber 9.

Further, in this embodiment the inlet and the main heat transfer passage sections can 5 be with or without catalytic material.

Also in this embodiment, the catalytic device may comprise an insulating material 12 between the inlet passage 11 and the main reaction passage section 3 in order to reduce or control the heat exchange between the gases in these passages.

10 The catalytic material can be of one or several kinds preferably from the Platinum metal group such as Platinum (Pt), Palladium (Pd), Rhodium (Rh) or similar metals or metal alloys that are well-known by skilled persons within the area of oxidation catalytic material in catalytic devices. The different type of metals or metal alloys 15 may be used together in a catalytic device e.g. Rhodium for nitrogen oxide reduction and Platinum and Palladium for carbon monoxide reduction.

Further, catalytic material involving different types of metal oxides may be used. Examples of metal oxides are Aluminium (Al), Gold (Au), Silver (Ag), Lead (Pb), 20 Zirconium (Zr), Copper (Cu), Cobalt (Co), Nickel (Ni), Iron (Fe), Cerium (Ce), Chrome (Cr), Tin (Sn), Manganese (Mn) and Rhodium (Rh) Oxides.

Even further, a combination of different catalytic materials may be used such as metal and/ metal alloys together with one or more metal oxides as described above. 25 The combination may be achieved by mixing the different materials or by positioning the different materials one after another in the catalytic device.

The catalytic device may comprise more than three passage sections e.g. four or five sections in which more sections however involve a significant increase in the structural complexity of the device as well as the costs. In an embodiment the 30 catalytic device comprises a last passage section, a second-last passage section and at

least two previous sections. The last and second-last and first passage sections correspond, respectively, to the main heat transfer, main reaction and the inlet passage section of the embodiment comprising three passages. The intermediate passage sections in the present embodiment may in construction correspond to any of 5 the three passage sections e.g. comprising catalytic material or not. Further, any construction details in connection with the passage sections revealed above or below may be integrated in the intermediate passage sections.

Fig. 4 illustrates a sectional view through the catalytic device of fig. 3 or fig. 5. It 10 applies for these embodiments (and the embodiment of fig. 2) that outermost under the last layer of plates, an insulating layer 13 can be installed in order to reduce the heat loss to the surroundings.

Further, the figure illustrates the inlet passage section 11 or the outlet passage section 15 22 surrounding the main reaction and the heat transfer passage sections 3, 5. The main reaction passage section is illustrated as a pipe with a circular cross section in which the section comprises catalytic material 4 (illustrated with similar hatched areas as fig. 2) and the main heat transfer passage section 5. The main heat transfer passage 5 is illustrated as a few number of pipes positioned in different patterns. 20 However, it shall be emphasised that the number of pipes preferably are between 50 and 250 (as stated above) and that the illustrated pipes (on this and the previous figure) only are a section of the total number of pipes. The illustrated patterns include triangular, quadrangular or similar symmetrical patterns (illustrated with dotted/solid lines) in which one or combinations of more patterns may be used in a passage 25 section of the catalytic device. The patterns may also be more or less random or freely positioned in the passage section of the catalytic device.

The patterns of pipes and the hydraulic diameter between the pipes are preferably chosen in order to achieve a low pressure loss.

The catalytic material may be deposit on the surface of ceramic, glass or metal fibres that form a tangled bundle of fibres or fibre wool (e.g. as illustrated in fig. 11). The tangled bundle of fibres or fibre wool may partly or totally fill the passage section but still allows the gas to flow through the passage section. Further, the catalytic 5 material may be deposit on the surface of ceramic, glass or metal surfaces that form a longitudinal monolith structure (e.g. as illustrated in fig. 13).

In a preferred embodiment of the invention the cross-sectional area of said main reaction passage section is between 0.5 and 100 times, such as between 10 and 25 10 times, preferably about 20 times, the cross-sectional area of said main heat transfer passage section and/or said inlet or outlet passage sections are between 0.5 and 100 times, the cross-sectional area of said main heat transfer passage section.

Further, the cross-sectional area of the main heat transfer passage section is between 15 0.5 and 10 times, such as 1.5 to 2.5 times, preferably about 2 times, the cross-sectional area of the inlet of the catalytic device, said inlet pipe being the exhaust pipe for the connected internal combustion engine.

The catalyst is not necessarily cylindrical as shown on fig. 2 to 5 but may be any 20 other shape depending on the requirements dictated by the application which the catalytic device is a part of. Examples of shapes may be spherical, quadrangular, corrugated or further shapes e.g. combinations of shapes or irregular shapes.

Fig. 5 illustrates another preferred embodiment of the catalytic device according to 25 the invention.

At the inlet 2, the gas is distributed to enter the main reaction passage section 3. In this section 3 the reaction takes place and the maximum temperature is achieved in the succeeding turning chamber 9 in which the gases turn from the main reaction 30 passage section 3 to the main heat transfer passage section 5. As in the previous embodiments the gases in the main heat transfer passage section 5 exchange heat to

the gases in the main reaction passage section 3 to heat up these gases. From main heat transfer passage section 5 the gases enter the second turning chamber 23 from which the gases enter the outlet passage section 22; Flowing in the outlet passage section the gases further exchange heat to the inlet part of the main reaction passage section 3 and thus helping to increase the temperature level of the reaction in the passage section 3. The temperature controlling characteristic and many of the other characteristics, such as the number of pipes and pattern shapes, of this embodiment is the same as in the previous embodiment of fig. 3.

- 10 Figs. 6a and 6b illustrate examples of temperature curves for the embodiments of the catalytic device in fig. 3 and 5.

Fig. 6a illustrates a temperature curve for the catalytic device of fig. 3 in which the gas enters through the inlet 2 with a temperature  $T_0$ . As the gas is directed through the inlet passage channel the gas in the succeeding main reaction passage section will preheat the gas to a temperature  $T_1$  at the turning chamber before the main reaction passage section. The gas is further preheated in the main reaction passage section by the counterflowing gas in the main heat transfer passage section. At the end of the main reaction passage section the combustible material of the gas reacts with the catalytic material and the temperature jumps to  $T_2$  just before entrance to the main heat transfer passage section. The gas temperature drops as the gas flows through the main heat transfer passage section and ends with  $T_{out}$  at the outlet of the catalytic device.

- 25 Fig. 6b illustrates a temperature curve for the catalytic device of fig. 5 in which the gas enters through the inlet 2 with a temperature  $T_0$ . As the gas is directed through the main reaction passage section the gas will be preheated by gas in the succeeding main heat transfer and outlet passage sections. The outlet passage section will only add to the preheating until the gas in the main reaction passage section has reached the temperature of the outlet passage section. At the end of the main reaction passage section the combustible material in the gas reacts with the catalytic material and

courses a temperature jump. In the turning chamber between the main reaction and the main heat transfer passage section the temperature  $T_1$  is reached. The gas is counterflowing in the heat transfer passage section and transferring heat to the gas in the main reaction passage section and thus has the temperature dropped to  $T_2$  at the 5 entrance to the outlet passage section.

Figs. 7a and 7b illustrate a further preferred embodiment of the catalytic device according to the invention. The catalytic device comprises a rather quadrangular shape.

10

Fig. 7a illustrates the catalytic device (B - B sectional view) in which the inlet passage section 11 is divided into two outer parts positioned on top and on bottom of the second passage section. The main reaction passage section is partly or totally filled with carrier means such as tangled bundle of fibres or fibre wool deposited 15 with catalytic material 4 (illustrated with a hatched area). Inside the main reaction passage section a number of aligned pipes of a main heat transfer passage section are positioned such as 7 aligned pipes. The pipes of the main heat transfer passage section are further spaced apart with the same distance in order to avoid gas pressure build up occurring in a part of the main reaction and the main heat transfer passage 20 section. The main heat transfer passage sections comprise a quadrangular shape with rounded corners. It shall be emphasized that the number of aligned pipes may be changed to any advantageous number such as between 5 and 50 pipes.

Fig. 7b illustrates the A - A sectional view of the catalytic device illustrated in fig. 25 5a. The figure illustrates how the inlet passage section after the inlet 2 divides into the two separate parts of the inlet passage section 11. Each parts of the inlet passage section 11 is connected to a main reaction passage section 3 that is directed along the inlet passage section 11 with a wall in common. As the gas will flow in opposite direction in the inlet and the main reaction passage section, respectively, it is possible 30 to establish a heat exchange through the common wall. The main reaction passage 3 ends in a common main heat transfer passage section 5 that once again directs the gas

in the opposite direction allowing the gas in the main reaction and the main heat transfer passage section 3, 5 to heat exchange through a common wall 6. After passing through the main heat transfer passage section, the gas is directed to the outlet 8.

5

Fig. 8 illustrates a sectional view of an even further preferred embodiment of the catalytic device according to the invention. The catalytic device is cylindrical with a circular cross section.

- 10 The circular cross section illustrates the outer inlet passage section 11 fully surrounding the main reaction and the main heat transfer passage sections 3, 5 in which the main heat transfer passage section is integrated into the second passage section. The main heat transfer passage sections comprise rather ellipsis shaped cross sections in which the height of the sections is different for some of the main heat  
15 transfer passage sections. With the different sizes it is possible to fill out most of the second passage section with third passage sections.

- Fig. 9 illustrates a section or pipe of a passage section with a corrugated and a smooth surface shape. With the corrugated section shape it is possible to establish a  
20 larger surface but also with a larger pressure loss than the smooth surface shape. The size of the illustrated cross sections – width and/or height as well as the number and depth of the corrugations – may be varied in order to achieve preferred embodiments of the catalytic device according to the invention.

- 25 Further, the corrugated and the non-corrugated section are illustrated with an angular or edged surface indicating that the sections are manufactured in one metal plate. The plate is bend into shape and subsequently joined together e.g. by welding.

- 30 The passage section also comprises a number of indentations in the surface in which the indentations are illustrated as longitudinal and parallel in the direction of the

section. However, the indentations may also be diagonal in relation to the direction of the section and cross-layered from plate to plate.

Fig. 10 illustrates a special embodiment in which a wall flows filter 14 is integrated 5 into the catalytic device according to the invention.

The wall flow filter 14 is integrated into the container c of the catalytic device 1 in the main reaction passage section. With the positioning of the wall flow filter, a number of common channels are established between the filters that work as main 10 heat transfer passage sections 5. The inlet passage section 11 is shown with a dotted line in order to illustrate that the section surrounds the rest of the sections. The inlet passage section is connected to the main reaction passage section 3 in which the section comprises the wall flow filter. The (numerous) common walls 16 between the inlet and outlet of the filters are porous allowing the gas 15 to penetrate from the 15 inlet to the outlet. The common walls comprise catalytic material on the surface, integrated in the wall or a combination hereof allowing the gas to be purified in the passage of the filter.

The filter is preferably a number of parallel pipes or the like establishing a triangular, 20 chessboard (as illustrated in the figure) or honeycomb cross-section patterns as a type of monolith. The pipes are all closed in one end in which some pipes are closed in the opposite end of the end that the gas enters and the rest are closed in the end in which the gas enters.

25 The heat exchange through the walls, porous or non-porous, ensures that heat is exchanged between the gas in the respective passage sections.

Fig. 11 illustrates a sectional view of a passage section which includes a number of carrier means in the shape of longitudinal fibres deposited with catalytic material.

The figure illustrates that the main reaction passage section is filled with a large number of thin longitudinal fibers 17 as well as pipes 5 of the main heat transfer passage section. The fibers comprise catalytic material 4 on the surface where the gas flows by and reacts with catalytic material 4.

5

The magnified sectional view illustrates that the fibres still form a tangled bundle of fibres or fibre wool but are substantially extended in a longitudinal direction. With the preferred direction of the fibres it is possible to minimize the pressure loss through the passage section. The bundle of fibres may also extend in other directions 10 or just freely but with a higher pressure loss as the gas flow will experience a higher flow resistance.

In order to enhance the catalytic process, the deposit surface must be as large as possible. Especially with the use of fibres including catalytic material 4 on the outer 15 surface it is possible to achieve large surfaces and a good heat transfer through the main reaction passage section toward the walls transferring the heat to other passage sections.

Fig. 12 illustrates a sectional view of passage sections including a number of carrier 20 means deposited with catalytic material.

The carrier means are illustrated as a number of regular or irregular balls 18 coated with catalytic material 4. The carrier means are positioned in layers (a layer L illustrated with dotted lines on the figure) across one of said passage sections, each of 25 said layers comprises 2 to 6 balls, such as 2 to 4 and preferably 2 or 3 between adjacent pipes 5.

The carrier means may also be other shapes such as spherical, cylindrical or quadrangular shapes as well as saddle, ring or any further regular or irregular shapes. 30 With the use of balls or other shapes it is possible to achieve large surfaces and a

good heat transfer through the main reaction passage section toward the walls transferring the heat to other passage sections.

5 The carrier means 18 are preferably made in metal, ceramic, glass or other heat resistant materials as well as combinations of the mentioned materials.

Fig. 13 illustrates sectional view of a passage section comprising a longitudinal monolith structure. The structure comprises very thin pipes or walls positioned in a pattern such as a honeycomb pattern as illustrated.

10 The pipes of the main heat transfer passage section 5 are fully surrounded by the honeycomb structure of the main reaction passage section 3.

15 Fig. 14 illustrates a sectional view of a passage section comprising a structure with wall flow filters and longitudinal fibres 20. It shall be emphasised that other types of carrier means such as the above mentioned may replace the fibres.

20 The main reaction passage section is divided into two parts in which one part is filled with one or more wall flow filters (e.g. 1/3) and the other part with longitudinal fibers. The section may also be divided into further parts that may be filled by any preferred carrier means.

Fig. 15 illustrates schematically an embodiment of the catalytic device including different characterizing data of the device.

25 The catalytic device comprises a length X and a height or diameter Y. Further, the device comprises a number of carrier means, said means having a size D.

30 In a first embodiment that preferably is used in an application involving a gas engine e.g. in connection with a combined power and heat plant, the plant may have a nominal electric effect of 30 kW.

The length X is approximately 1.0 meter and the height or diameter Y is approximately 0.3 meter. The UHC value (unburned hydrocarbon) is between 3 and 8 % of the firing rate to the engine.

5

An application with a gas engine may in a preferred embodiment include a catalytic device with at least 50 pipes in a passage section as illustrated in fig. 3 to 5 or 15. The diameter of the pipes is approximately 6 to 8 millimeters.

- 10 In a second embodiment that preferably is used in an application involving a gas engine e.g. in connection with a combined power and heat plant, the plant may have a nominal electric effect of 500 kW.

- 15 The length X is approximately 1.5 meter and the height or diameter Y is approximately 0.7 meter. The UHC value (unburned hydrocarbon) is between 3 and 8 % of the firing rate to the engine.

- 20 An application with a gas engine may in a preferred embodiment include a catalytic device with at least 200 pipes in a passage section as illustrated in fig. 3 to 5 or 15. The diameter of the pipes is approximately 8 to 12 millimeters.

In a third embodiment that preferably is used in an application involving an internal petrol fuelled combustion engine e.g. in connection with vehicles.

- 25 The length X is approximately 0.2 to 0.4 meter and the height or diameter Y is approximately 0.2 meter.

- 30 The UHC value (unburned hydrocarbon) is between 0.5 and 5 % of the firing rate to the petrol combustion engine. The value can in a preferred embodiment be raised to approximately 5 to 10 % in order to achieve higher temperatures inside the catalytic device by burning further hydrocarbons inside the device. Higher temperatures in the

catalytic device mean that catalytic material is saved. Higher values than 10 % of the firing rate will affect the efficiency of the petrol combustion engine.

An application with a petrol combustion engine may in a preferred embodiment  
5 include a catalytic device with at least 50 pipes in a passage section as illustrated in fig. 3 to 5 or 15.

In a fourth embodiment that preferably is used in an application involving internal diesel fuelled combustion engine e.g. in connection with vehicles.

10 The length X is approximately 1 meter and the height or diameter Y is approximately 0.3 meter.

15 The UHC value (unburned hydrocarbon) is normally between 0.5 and 3 % of the firing rate of the diesel combustion engine but can in a preferred embodiment be raised to approximately 5 % in order to achieve higher temperatures inside the catalytic device by burning further hydrocarbons inside the device.

Especially, in order to remove the ultra fine particles efficiently from the diesel  
20 exhaust gas, it is necessary to use catalytic material coated on very large surfaces such as the embodiment illustrated in fig. 11 or 14.

It shall be emphasized that the above-mentioned embodiments are only examples of applications in which the catalytic device can be used. Further, the data of the  
25 embodiments are only examples of values that may be used in specific applications. In the applications and in other applications different data and values may also be used if found suitable.

Fig. 16 illustrates a further application including a catalytic device according to the  
30 invention.

The application involves the means of fig. 1 in which a fuel supply line S4 is added between the fuel supplying means and the catalytic device. The line is added in order to illustrate the possibility of raising the UHC value in the gas by supplying (unburned) fuel to the catalytic device. The fuel may be delivered to the catalytic  
5 device and the entered gas by a separate valve or spout in the catalytic device, or simply by controlling the combustion process of the combustion engine allowing the exhaust gas to achieve a higher UHC value.

10 The fuel supply line S4 may also deliver the extra fuel to a position in between the fuel supplying means and the catalytic device. For example may the fuel be added to the exhaust gas just before entering the catalytic device e.g. by spraying the fuel into the exhaust gas.

15 Fig. 17 illustrates a flow diagram of a preferred embodiment of the invention.  
The flow diagram illustrates the treatment of the exhaust gas in which one or more temperatures of the catalytic device controls the flow path of the gas.

20 The temperature or temperatures may be measured inside one or more of said passage sections, one or more turning chambers and/or said inlet. The temperature is compared with a pre-established temperature threshold value. A temperature below a threshold value will establish a connection to the outlet of the catalytic device (e.g. through a valve as will be explained in the text below). Temperature below the temperature threshold value will usually occur in a short time period at the start-up of  
25 the catalytic device. The exhaust gas will during the period react with the catalytic material in the main reaction passage section and thus causing an increase in the temperature.

30 The connection be will closed as a higher temperature than the threshold value is achieved and thus force the exhaust gas through the normal path of the catalytic device as will be explained in the text below.

Fig. 18 illustrates a first preferred embodiment of the catalytic device with temperature valve control means.

- 5 The figure illustrates a catalytic device 1 corresponding to the device of fig. 2 in which the inlet 2 is positioned at one side of the device. From the inlet the exhaust gas is initially directed through the first passage (the main reaction passage section 3) to the turning chamber 9. Normally the gas would turn and flow through the further passages but a temperature dependent valve control means 26 is open due to the  
10 lower initial temperature of the catalytic device.

The surrounding temperature controls the condition of the temperature dependent valve control means 26. Temperatures below a threshold value will open the valve and a higher temperature will close it.

- 15 The gas will thus initially flow through a valve pipe section 27 including the valve 26 and continue to the exterior via an exhaust pipe section 28. The temperature dependent valve control means 26 will subsequently close as the catalytic reaction in the main reaction passage section 3 quickly heats up the catalytic device. The gas  
20 will hereafter follow a normal path through the catalytic device e.g. as described in connection with the figs. 2 and 3. When the gas reaches the outlet chamber 7 it is transferred to an outlet pipe section 25 which directs the gas to the exhaust pipe section 28 in front of the now closed temperature dependent valve control means 26.

- 25 Figs. 19 and 20 illustrate schematically preferred embodiments including a temperature dependent valve control means 26.

- Fig. 19 illustrates the temperature dependent valve control means 26 in a position corresponding to the illustrated in fig. 18. However, the catalytic device 1 as such  
30 may be any catalytic device e.g. one of the devices illustrated in the previous figures.

Fig. 20 illustrates schematically a catalytic device 1 with the temperature valve control means positioned differently.

The figure illustrates how the temperature dependent valve control means 26 can be  
5 positioned in proximity of the outlet chamber 7 instead of the turning chamber 9  
(illustrated in fig. 19).

As illustrated in figs. 19 and 20 the pipe sections are preferably connected to the  
catalytic device 1 at the turning chamber 9 and the outlet chamber 7, respectively.  
10 Other connection positions are also possible e.g. both connections being at different  
positions in the outlet chamber. However, the embodiments of the figures are  
preferred in order to achieve a functionality of the temperature dependent valve  
control means 26 in which the valve responds quickly to temperature changes.  
15 Fig. 21 illustrates a preferred embodiment of the temperature valve control means.  
The valve includes an anchoring point 30 and a closing member 31 for the valve  
control means which are mutually connected by temperature dependent connection  
means 29. The temperature dependent connection means 29 may be chosen between  
a number of different components comprising the characteristic of changing size at  
20 temperature exposure.

The figure illustrates an example with the temperature dependent connection means  
29 as an internal and passive solution involving a helical formed spring or coil. The  
spring is preferably made in a bimetal that will contract at temperatures above a  
25 threshold value.

The closing member 31 will be pulled closer to the anchoring point 30 at a rising  
temperature as the temperature dependent connection means 29 connects the two.  
The closing member 31 will be retracted to a position in which it closes the opening  
30 illustrated in figure at a temperature above the threshold value.

The functionality of the valve is:

- 1) The valve 26 controls the flow through the catalytic device. When the valve 26 is open, the exhaust gas flows from the inlet through a fewer number of passage sections of the catalytic device and directly to the outlet pipe section. When the valve 26 closes, the exhaust gas is forced down through the necessary or desired sections of the catalytic device.  
5
- 2) The valve 26 closes when the desired temperature in turning chamber 9 is achieved which preferably will mean when the catalytic device is working.  
10
- 3) The valve 26 can as mentioned above be controlled by a bimetal spring 29 that closes at a high temperature (a ramp closing over a temperature interval). The bimetal spring 29 is preferably placed so that it is kept warm by the exhaust gas flowing from the outlet pipe section 25 when the valve is closed.  
15

The temperature dependent connection means 29 may also be established by a partly external and active solution involving temperature measurements and electric power supply for the valve 26.

- 20
- The valve 26 can be controlled by temperature measurements in the turning chamber 9 and the valve closes when the temperature is above a pre-established temperature value. Measuring the temperature difference between the turning chamber 9 and the inlet or the inlet pipe 2 can also be used in controlling the valve 26. When the  
25 temperature in the turning chamber 9 exceeds the temperature in the inlet or the inlet pipe 2, the valve closes.

- 30
- The temperature signals are supplied to the electric power supply which establishes a power signal to the means controlling the valve e.g. magnetic means controlling the position of the closing member 31.

The valve opening may be the entrance to the valve pipe section 27 or an opening in the valve pipe section 27. Further, the valve opening and the temperature dependent valve control means 26 may be an integrated part of the catalytic device as will be explained in connection with fig. 21.

5

Fig. 22 illustrates the integration of the temperature valve control means 26 in an embodiment of the catalytic device 1.

10 The turning chamber 9 is illustrated with an opening allowing gas to enter from the turning chamber 9 to the outlet passage section 22 and the outlet pipe 8. The temperature dependent valve control means 26 is positioned in the opening in order to control the accessibility between the turning chamber 9 and the outlet passage section 22. The opening defined by the chamber walls may comprise a metal lining or a similar material to establish an airtight closure between the walls and the closing  
15 member 31.

20 Fig. 23 illustrates an embodiment in which the temperature probes 36 are positioned inside one or more of said passage sections, one or more turning chambers and/or said inlet. The probes are connected to temperature measuring means 33. The temperature measuring means 33 establishes control signals that control the valve 26 through valve control means 34. The valve control means 34 may e.g. be the power supply of the valve.

25 Fig. 24 illustrates a further preferred embodiment of the catalytic device. The figure illustrates an embodiment with a fourth passage surrounding the three passages e.g. the three passages of the catalytic device 1 illustrated in fig. 3. In the inlet passage 11 a catalytic device for NOx-reduction can be placed. In the main reaction passage section 3 an oxidation of CO, unburned fuel, such as unburned hydrocarbons, and possibly particles (PM) takes place. In the main heat transfer passage section 5 a heat exchange with passage 3 takes place that increases the temperature to a maximum in 30 9. In passage 22 an additional heat exchange with passage 11 takes place and

35

insulation can be eliminated or minimised as 22 protects against heat loss from the passage 11 and the passage 11 protects against heat loss from passages 3 and 5. The fourth passage is illustrated as a last of the outlet passage sections 22 in which the passage transfers the gas to the outlet pipe 8.

5

Generally, the outlet 8 or outlet pipe 8 should be understood as a term defining the outlet of the catalytic device e.g. including the pipe sections 25-28.

Generally, the term "opening" in connection with the valve e.g. "the opening 35"  
10 should be understood as the opening that the valve opens or closes.

The figures are not of dimensional accuracy, and all dimensions and materials must  
be determined for the actual use.

15 The invention has been exemplified above with reference to specific examples.  
However, it should be understood that the invention is not limited to the particular  
examples described above but may be used in connection with a wide variety of  
applications. Further, it should be understood that especially the shapes of the  
catalytic device and especially the passage sections according to the invention may  
20 be designed in a multitude of varieties within the scope of the invention as specified  
in the claims.

**Claims**

1. Method for treatment of a fluid quantity including chemical reacting means such as combustible materials above a certain minimum quantity in a catalytic device, said method comprises the steps of
  - 5 entering said fluid quantity into the catalytic device through an inlet,
  - 10 controlling the temperature in one or more passage sections of said catalytic device, and
  - 15 emitting the treated fluid quantity from the catalytic device through an outlet.
- 15 2. Method according to claim 1 wherein the temperature directly or indirectly controls the opened or closed position of at least one valve.
- 20 3. Method according to claim 2 wherein said at least one valve controls the flow path of the fluid in the catalytic device.
- 25 4. Method according to claim 2 or 3 wherein said at least one valve opens or closes a connection between a main reaction passage section and the outlet as a result of the temperature.
- 30 5. Method according to any of claims 2 to 4 wherein said at least one valve opens or closes in response to the temperature of the fluid flowing by temperature dependent connection means in said at least one valve.
6. Method according to claim 5 wherein the fluid always flows through, by or in the proximity of the temperature dependent connection means.

7. Method according to any of claims 1 to 6 wherein a valve control signal is established by measuring the temperature inside one or more of said passage sections, one or more turning chambers and/or said inlet.
- 5 8. Method according to claim 7 wherein the valve control signal is established on the basis of the temperature difference between one or more of said passage sections, one or more turning chambers and/or said inlet.
9. Method according to claim 7 or 8 wherein the valve control signal is 10 established in relation to a predefined temperature threshold signal.
10. Method according to any of claims 1 to 9 wherein said main reaction passage section heat exchanges with a main heat transfer passage section, and/or where the main reaction passage section heat exchanges with one or more preceding inlet passage sections and/or one or more succeeding outlet 15 passage sections.
11. Method according to any of claims 1 to 10 wherein the fluid quantity is directed through the succeeding passage sections in counterflow. 20
12. Method according to any of claims 1 to 11 wherein further combustible material is added directly or indirectly to the catalytic device.
13. Method for treatment of a fluid quantity including chemical reacting means such as combustible materials above a certain minimum quantity in a catalytic device, said method comprises the steps of 25  
entering said fluid quantity into the catalytic device through an inlet,
- 30 directing said fluid quantity through at least three passage sections of said catalytic device in which at least one section includes catalytic material of

one or more kinds in which the catalytic material reacts with and/or enhances the reactions of said combustible materials,

5 heating or cooling said fluid quantity in said at least three passage sections by internal heat exchange in said catalytic device between said sections, and

emitting the treated fluid quantity from the catalytic device through an outlet.

14. Method according to claim 13 wherein a main reaction passage section heat exchanges with a main heat transfer passage section, and where the main reaction passage section heat exchanges with one or more preceding inlet passage sections and/or one or more succeeding outlet passage sections.

15. Method according to claim 13 or 14 wherein the fluid quantity is directed through the succeeding passage sections in counterflow.

16. Method according to any of claims 13 to 15 wherein further combustible material is added directly or indirectly to the catalytic device.

20 17. Catalytic device (1) for treatment of a fluid quantity including chemical reacting means such as combustible materials above a certain minimum quantity, said device comprising

25 at least one inlet and outlet for said fluid quantity and at least two passage sections (3, 5, 11, 22) being mutually connected, and

at least one section (3) of said passage sections (3, 5, 11, 22) includes catalytic material (4) of one or more kinds,

30 characterised in that

said device further comprises means for controlling the temperature in one or more of said passage sections (3, 5, 11, 22).

18. Catalytic device (1) according to claim 17, characterised in that said means for controlling the temperature includes positioning of said passage sections (3, 5, 11, 22) in order to form at least one internal heat exchanger (b) with mutual heat exchange between the sections (3, 5, 11, 22).  
5
19. Catalytic device (1) according to claim 17 or 18, characterised in that said catalytic device comprises at least three passage sections (3, 5, 11, 22).  
10
20. Catalytic device (1) according to claim 19, characterised in that said catalytic device comprises three passage sections (3, 5, 11, 22).  
15
21. Catalytic device (1) according to claim 19, characterised in that said catalytic device comprises four passage sections (3, 5, 11, 22).
22. Catalytic device (1) according to claim 21, characterised in that said fourth passage section (22) is the last outlet passage section surrounding the previous passage sections (3, 5, 11, 22).  
20
23. Catalytic device (1) according to any of claims 17 to 22, characterised in that said device comprises a container (c) including said inlet, said passage sections and said outlet.  
25
24. Catalytic device (1) according to any of claims 17 to 23, characterised in that at least one turning chamber (9) between two of said passage sections (3, 5) comprises a connection to the exhaust pipe section (28) controlled by at least one valve (26).  
30

25. Catalytic device (1) according to claim 24, characterised in that each of said at least one valve (26) comprises a closing member (31) and temperature dependent connection means (29) connecting said closing member and an anchoring point (30).

5

26. Catalytic device (1) according to claim 25, characterised in that said temperature dependent connection means (29) is a spring made in bimetal or a similar temperature dependent material.

10 27. Catalytic device (1) according to claim 25 or 26, characterised in that said temperature dependent connection means (29) partly or totally is positioned in the outlet pipe (8) such as the outlet passage sections (22), valve pipe section (27), exhaust pipe section (28) or the outlet pipe section (25).

15

20 28. Catalytic device (1) according to any of claims 20 to 23, characterised in that said outlet pipe (8) comprises a valve pipe section (27) including at least one valve, an outlet pipe section (25) connected to the outlet passage section (22), in which both pipe sections are connected to an exhaust pipe section (28).

25 29. Catalytic device (1) according to any of claims 20 to 23, characterised in that said temperature dependent connection means (29) partly or totally is positioned in proximity of the connection between said pipe sections (25, 27) or in the exhaust pipe section (28).

30 30. Catalytic device (1) according to any of claims 17 to 29, characterised in that said device includes temperature-measuring means (33, 36) measuring the temperature inside one or more of said passage sections, one or more turning chambers and/or said inlet.

31. Catalytic device (1) according to claim 30, characterised in that valve control means (34) controls the position of said at least one valve on the basis of temperature values from said temperature-measuring means (33, 36).
- 5
32. Catalytic device (1) according to any of claims 17 to 31, characterised in that said catalytic device comprises three passage sections (3, 5, 11, 22).
- 10
33. Catalytic device (1) according to any of claims 17 to 32, characterised in that said one or more inlet passage sections (11) is positioned above, alongside or outside said main reaction passage section (3) e.g. by surrounding said section.
- 15
34. Catalytic device (1) according to any of claims 17 to 33, characterised in that said one or more outlet passage sections (22) is positioned above, alongside or outside said main reaction passage section (3) e.g. by surrounding said section.
- 20
35. Catalytic device (1) according to any of claims 17 to 34, characterised in that said main reaction passage section (3) is positioned above, alongside or outside said main heat transfer passage section (5) e.g. by surrounding said section.
- 25
36. Catalytic device (1) according to any of claims 17 to 35, characterised in that at least one of said at least three passage sections, such as said main heat transfer passage section (5), comprises one or more substantially parallel pipes.
- 30

37. Catalytic device (1) according to claim 36, characterised in that said main heat transfer passage section (5) is integrated as a number of pipes in said main reaction passage section (3).
- 5 38. Catalytic device (1) according to claim 36 or 37, characterised in that said number of pipes is between 20 and 5000 pipes and preferably between 50 and 1000 pipes.
- 10 39. Catalytic device (1) according to any of claims 36 to 38, characterised in that said pipes form symmetrical patterns such as triangular, quadrangular or similar patterns or random patterns.
- 15 40. Catalytic device (1) according to any of claims 36 to 39, characterised in that said pipes is surrounded by catalytic material (4) deposited on one or more carrier means (17-21).
- 20 41. Catalytic device (1) according to any of claims 36 to 40, characterised in that said pipes comprise a circular, an oval, a triangular, a four-sided or any similar regular or irregular cross sectional shape.
- 25 42. Catalytic device (1) according to any of claims 17 to 41, characterised in that at least one of said three passage sections, such as said main heat transfer passage section (5), comprises one or more lamellar plates.
- 30 43. Catalytic device (1) according to claim 42, characterised in that said one or more lamellar plates form non-circular canals e.g. with a cross sectional shape formed by triangles, four sided shapes, combinations hereof or similar shapes.

44. Catalytic device (1) according to claim 42 or 43, characterised in that indentations in the surface of said one or more lamellar plates form longitudinal or diagonal patterns.

5

45. Catalytic device (1) according to any of claims 17 to 44, characterised in that said catalytic material (4) is deposited on one or more carrier means (17-21) in at least one of said at least three passage sections (3, 5, 11, 22).

10

46. Catalytic device (1) according to any of claims 17 to 45, characterised in that said one or more carrier means (17-21) are made in metal, ceramic, glass or other heat resistant materials as well as combinations of the mentioned materials.

15

47. Catalytic device (1) according to any of claims 17 to 46, characterised in that said one or more carrier means (18) include at least one shape such as spherical, cylindrical or quadrangular shapes as well as saddle, ring, regular or irregular shapes.

20

48. Catalytic device (1) according to any of claim 17 to 47, characterised in that said one or more carrier means (17-21) include a number of regular or irregular balls (18) in layers (L) across one of said passage sections, each layer being positioned perpendicularly between two adjacent pipes, and each of said layers comprising 2 to 6 balls, such as 2 to 4 and preferably between 2 and 3.

25

49. Catalytic device (1) according to any of claims 17 to 48, characterised in that said one or more carrier means (17-21) include monoliths (19, 21) or fibres (17, 20).

30

50. Catalytic device (1) according to claim 49, characterised in that said fibres (17, 20), deposit with said catalytic material form a tangled bundle of fibres partly or totally filling one or more of said passage sections.
- 5 51. Catalytic device (1) according to claim 49 or 50, characterised in that said monoliths (19, 21) or fibres (17, 20), deposit with said catalytic material (4) form longitudinal monoliths or fibres inside one or more of said passage sections.
- 10 52. Catalytic device (1) according to any of claims 17 to 51, characterised in that said main reaction passage section (3) of said at least three passage sections (3, 5, 11, 22) comprises one or more kinds of said catalytic material (4) deposit on said carrier means (17-21).
- 15 53. Catalytic device (1) according to any of claims 17 to 52, characterised in that said one or more inlet and/or outlet passage sections (11, 22) of said at least three passage sections (3, 5, 11, 22) comprises one or more kinds of said catalytic material (4) deposit on said carrier means (17-21).
- 20 54. Catalytic device (1) according to any of claims 17 to 53, characterised in that one or more of said at least three passage sections comprise combined carrier means including wall flow filters (21), fibres (17, 20), balls (18) and/or monoliths (19) e.g. 1/3 passage section as wall flow filters and the rest of the section as fibres, balls or monoliths.
- 25 55. Catalytic device (1) according to claim 54, characterised in that said combined carrier means are positioned in continuation of each other through one or more of said at least three passages.
- 30

56. Catalytic device (1) according to any of claims 17 to 55, characterised in that said catalytic material (4) includes metal or metal alloys from the Platinum metal group such as Platinum (Pt), Palladium (Pd), Rhodium (Rh) or combinations hereof.
- 5  
57. Catalytic device (1) according to any of claims 17 to 56, characterised in that said catalytic material (4) includes metal oxides such as Gold (Au), Platinum (Pt), Silver (Ag), Aluminium (Al), Lead (Pb), Zirconium (Zr), Copper (Cu), Cobalt (Co), Nickel (Ni), Iron (Fe),  
10 Cerium (Ce), Chrome (Cr), Tin (Sn), Manganese (Mn) and Rhodium (Rh) Oxides or combinations hereof.
58. Catalytic device (1) according to claim 56 or 57, characterised in that said catalytic material (4) includes combinations of metal or  
15 metal alloys from the Platinum metal group and metal oxides.
59. Catalytic device (1) according to any of claims 17 to 58, characterised in that said main reaction passage section (3) heat exchanges with said main heat transfer passage section (5) of said at  
20 least three passage sections (3, 5, 11, 22).
60. Catalytic device (1) according to claim 59, characterised in that said main reaction passage section (3) heat exchanges with said main heat transfer passage section (5) in counterflow.  
25
61. Catalytic device (1) according to any of claims 17 to 60, characterised in that said main reaction passage section (3) heat exchanges with said one or more previous inlet and/or succeeding outlet passage sections (11, 22).

62. Catalytic device (1) according to claim 61, characterised in that said main reaction passage section (3) heat exchanges with said one or more inlet passage sections (11) in counterflow.
- 5 63. Catalytic device (1) according to claim 61, characterised in that said main reaction passage section (3) heat exchanges with said one or more outlet passage sections in concurrent flow.
- 10 64. Catalytic device (1) according to any of claims 17 to 63 characterised in that said device comprises at least one layer of insulation (12) between said at least three passage sections (3, 5, 11, 22).
- 15 65. Catalytic device (1) according to claim 64, characterised in that said at least one layer of insulation (12) is positioned between said main reaction passage section (3) and said one or more inlet passage sections (11).
- 20 66. Catalytic device (1) according to any of claims 17 to 65, characterised in that the cross-sectional area of said main reaction passage section (3) is between 0.5 and 100 times, such as between 10 and 25 times, preferably about 20 times, the cross-sectional area of said main heat transfer passage section (5) and/or said inlet or outlet passage sections (11, 22) are between 0.5 and 100 times, the cross-sectional area of said main heat transfer passage section (5).
- 25 67. Catalytic device (1) according to any of claims 17 to 66 characterised in that the cross-sectional area of the main heat transfer passage section (5) is between 0.5 and 10 times, such as 1.5 to 2.5 times, preferably about 2 times, the cross-sectional area of the inlet (2) of

the catalytic device, said inlet pipe (2) being the exhaust pipe for the connected internal combustion engine.

68. Catalytic device (1) according to any of claims 17 to 67,  
5 characterised in that at least one of said passage sections (3, 5, 11, 22) comprises one or more wall flow filters (21) with numerous porous walls (16) allowing fluid quantity (15) to penetrate through the walls.
- 10 69. Catalytic device (1) according to any of claims 17 to 68  
characterised in that further combustion material is added to the device, e.g. through a fuel line (S4) connected to the fuel tank and the fuel supplying means (S1), or through adding further combustion material to the fluid quantity.  
15
70. Catalytic device (1) for treatment of a fluid quantity including chemical reacting means such as combustible materials above a certain minimum quantity, said device comprising  
20 a container (c) including at least one inlet and outlet for said fluid quantity,  
characterised in that  
25 said container further comprises at least three passage sections (3, 5, 11, 22)  
being mutually connected,  
where at least one section (3) of said passage sections (3, 5, 11, 22) includes catalytic material (4) of one or more kinds, and

where the positioning of said passage sections (3, 5, 11, 22) forms at least one internal heat exchanger (h) with mutual heat exchange between the sections (3, 5, 11, 22).

- 5 71. Catalytic device (1) according to claim 70, characterised in that said catalytic device comprises three passage sections (3, 5, 11, 22).
72. Catalytic device (1) according to claim 70 or 71, characterised in that said one or more inlet passage sections (11) is positioned above, alongside or outside said main reaction passage section (3) e.g. by surrounding said section.
- 10 73. Catalytic device (1) according to any of claims 70 to 72, characterised in that said one or more outlet passage sections (22) is positioned above, alongside or outside said main reaction passage section (3) e.g. by surrounding said section.
- 15 74. Catalytic device (1) according to any of claims 70 to 73, characterised in that said main reaction passage section (3) is positioned above, alongside or outside said main heat transfer passage section (5) e.g. by surrounding said section.
- 20 75. Catalytic device (1) according to any of claims 70 to 74, characterised in that at least one of said at least three passage sections, such as said main heat transfer passage section (5), comprises one or more substantially parallel pipes.
- 25 76. Catalytic device (1) according to claim 75, characterised in that said main heat transfer passage section (5) is integrated as a number of pipes in said main reaction passage section (3).
- 30

77. Catalytic device (1) according to claim 75 or 76, characterised in that said number of pipes is between 20 and 5000 pipes and preferably between 50 and 1000 pipes.
- 5 78. Catalytic device (1) according to any of claims 75 to 77, characterised in that said pipes form symmetrical patterns such as triangular, quadrangular or similar patterns or random patterns.
- 10 79. Catalytic device (1) according to any of claims 75 to 78, characterised in that said pipes is surrounded by catalytic material (4) deposited on one or more carrier means (17-21).
- 15 80. Catalytic device (1) according to any of claims 70 or 79, characterised in that said pipes comprise a circular, an oval, a triangular, a four-sided or any similar regular or irregular cross sectional shape.
- 20 81. Catalytic device (1) according to any of claims 70 to 80, characterised in that at least one of said three passage sections, such as said main heat transfer passage section (5), comprises one or more lamellar plates.
- 25 82. Catalytic device (1) according to claim 81, characterised in that said one or more lamellar plates form non-circular canals e.g. with a cross sectional shape formed by triangles, four sided shapes, combinations hereof or similar shapes.
- 30 83. Catalytic device (1) according to claim 81 or 82, characterised in that indentations in the surface of said one or more lamellar plates form longitudinal or diagonal patterns.

84. Catalytic device (1) according to any of claims 70 to 83,  
characterised in that said catalytic material (4) is  
deposited on one or more carrier means (17-21) in at least one of said at least  
5 three passage sections (3, 5, 11, 22).
85. Catalytic device (1) according to any of claims 70 to 84,  
characterised in that said one or more carrier means  
(17-21) are made in metal, ceramic, glass or other heat resistant materials as  
10 well as combinations of the mentioned materials.
86. Catalytic device (1) according to any of claims 70 to 85,  
characterised in that said one or more carrier means  
(18) include at least one shape such as spherical, cylindrical or quadrangular  
15 shapes as well as saddle, ring, regular or irregular shapes.
87. Catalytic device (1) according to any of claim 70 to 86,  
characterised in that said one or more carrier means  
(17-21) include a number of regular or irregular balls (18) in layers (L) across  
20 one of said passage sections, each layer being positioned perpendicularly  
between two adjacent pipes, and each of said layers comprising 2 to 6 balls,  
such as 2 to 4 and preferably between 2 and 3.
88. Catalytic device (1) according to any of claims 70 to 87,  
25 characterised in that said one or more carrier means  
(17-21) include monoliths (19, 21) or fibres (17, 20).
89. Catalytic device (1) according to claim 88, characterised in  
that said fibres (17, 20), deposit with said catalytic material form a  
30 tangled bundle of fibres partly or totally filling one or more of said passage  
sections.

90. Catalytic device (1) according to claim 88 or 89, characterised in that said monoliths (19, 21) or fibres (17, 20), deposit with said catalytic material (4) form longitudinal monoliths or fibres inside one or more of said passage sections.
- 5
91. Catalytic device (1) according to any of claims 70 to 90, characterised in that said main reaction passage section (3) of said at least three passage sections (3, 5, 11, 22) comprises one or more kinds of said catalytic material (4) deposit on said carrier means (17-21).
- 10
92. Catalytic device (1) according to any of claims 70 to 91, characterised in that said one or more inlet and/or outlet passage sections (11, 22) of said at least three passage sections (3, 5, 11, 22) comprises one or more kinds of said catalytic material (4) deposit on said carrier means (17-21).
- 15
93. Catalytic device (1) according to any of claims 70 to 92, characterised in that one or more of said at least three passage sections comprise combined carrier means including wall flow filters (21), fibres (17, 20), balls (18) and/or monoliths (19) e.g. 1/3 passage section as wall flow filters and the rest of the section as fibres, balls or monoliths.
- 20
94. Catalytic device (1) according to claim 93, characterised in that said combined carrier means are positioned in continuation of each other through one or more of said at least three passages.
- 25
95. Catalytic device (1) according to any of claims 70 to 94, characterised in that said catalytic material (4) includes metal or metal alloys from the Platinum metal group such as Platinum (Pt), Palladium (Pd), Rhodium (Rh) or combinations hereof.
- 30

96. Catalytic device (1) according to any of claims 70 to 95,  
characterised in that said catalytic material (4) includes  
metal oxides such as Gold (Au), Platinum (Pt), Silver (Ag), Aluminium (Al),  
5 Lead (Pb), Zirconium (Zr), Copper (Cu), Cobalt (Co), Nickel (Ni), Iron (Fe),  
Cerium (Ce), Chrome (Cr), Tin (Sn), Manganese (Mn) and Rhodium (Rh)  
Oxides or combinations hereof.
97. Catalytic device (1) according to claim 95 or 96, characterised  
10 in that said catalytic material (4) includes combinations of metal or  
metal alloys from the Platinum metal group and metal oxides.
98. Catalytic device (1) according to any of claims 70 to 97,  
characterised in that said main reaction passage section  
15 (3) heat exchanges with said main heat transfer passage section (5) of said at  
least three passage sections (3, 5, 11, 22).
99. Catalytic device (1) according to claim 98, characterised in  
that said main reaction passage section (3) heat exchanges with said  
20 main heat transfer passage section (5) in counterflow.
100. Catalytic device (1) according to any of claims 70 to 99,  
characterised in that said main reaction passage section  
25 (3) heat exchanges with said one or more previous inlet and/or succeeding  
outlet passage sections (11, 22).
101. Catalytic device (1) according to claim 100, characterised in  
that said main reaction passage section (3) heat exchanges with said one  
or more inlet passage sections (11) in counterflow.

102. Catalytic device (1) according to claim 100, characterised in that said main reaction passage section (3) heat exchanges with said one or more outlet passage sections in concurrent flow.
- 5 103. Catalytic device (1) according to any of claims 70 to 102 characterised in that said device comprises at least one layer of insulation (12) between said at least three passage sections (3, 5, 11, 22).
- 10 104. Catalytic device (1) according to claim 103, characterised in that said at least one layer of insulation (12) is positioned between said main reaction passage section (3) and said one or more inlet passage sections (11).
- 15 105. Catalytic device (1) according to any of claims 70 to 104, characterised in that the cross-sectional area of said main reaction passage section (3) is between 0.5 and 100 times, such as between 10 and 25 times, preferably about 20 times, the cross-sectional area of said main heat transfer passage section (5) and/or said inlet or outlet passage sections (11, 22) are between 0.5 and 100 times, the cross-sectional area of said main heat transfer passage section (5).
- 20
- 25 106. Catalytic device (1) according to any of claims 70 to 105 characterised in that the cross-sectional area of the main heat transfer passage section (5) is between 0.5 and 10 times, such as 1.5 to 2.5 times, preferably about 2 times, the cross-sectional area of the inlet (2) of the catalytic device, said inlet pipe (2) being the exhaust pipe for the connected internal combustion engine.
- 30 107. Catalytic device (1) according to any of claims 70 to 106, characterised in that at least one of said passage

sections (3, 5, 11, 22) comprises one or more wall flow filters (21) with numerous porous walls (16) allowing fluid quantity (15) to penetrate through the walls.

- 5 108. Catalytic device (1) according to any of claims 70 to 107 characterised in that further combustion material is added to the device, e.g. through a fuel line (S4) connected to the fuel tank and the fuel supplying means (S1), or through adding further combustion material to the fluid quantity.

10

109. Use of a method for treatment of a fluid quantity comprising chemical reacting means such as combustible materials above a certain minimum quantity in a catalytic device according to any of claims 1 to 4 for cleaning exhaust gas from internal combustion engines.

15

110. Use of a method for treatment of a fluid quantity comprising chemical reacting means such as combustible materials above a certain minimum quantity in a catalytic device according to any of claims 1 to 16 for temperature regulation or control in connection with any exothermal or 20 endothermal chemical reaction in an industrial chemical application.

111. Use of a method for treatment of a fluid quantity comprising chemical reacting means such as combustible materials above a certain minimum quantity in a catalytic device according to any of claims 1 to 16 for 25 temperature regulation or control in or in connection with fuel cells.

112. Use of a catalytic device according to any of claims 17 to 108 in connection with combustion engines in vehicles such as engines fuelled by petrol, diesel, natural gas, bottled gas or any similar fuels.

30

113. Use of a catalytic device according to any of claims 17 to 108 in connection with stationary combustion engines such as engines fuelled by petrol, diesel, natural gas, bottled gas or any similar fuels such as in power plants e.g. combined heat and power plants.
- 5
114. Use of a catalytic device according to any of claims 17 to 108 in connection with any exothermal or endothermal chemical reaction in an industrial chemical application.
- 10 115. Use of a catalytic device according to any of claims 17 to 108 in temperature regulation or control in or in connection with fuel cells.

**Abstract**

The invention relates to a catalytic device with internal heat exchange that among other things can be used for vehicles with an internal combustion engine or for 5 stationary engines where there is a certain amount of unburned gas components in the exhaust that can be converted in the catalyst.

By the invention it is obtained that the maximum temperature in the catalyst is always nearly constant whatever the inlet temperature. Hereby, the catalyst can be 10 designed to work at a very specific temperature, by which it is possible, partly to ensure a better and safer burnout of the unburned components, and partly to save expenses for catalyst materials.

15 The exhaust gas is guided through the catalyst (1) by at least three passage sections that have a mutual internal heat exchange. In the main reaction passage section (3) there are catalytic materials (4) of one or several kinds, in which the gas can react, and in which the gases heat exchange with the succeeding main heat transfer passage section passage (5).

20 The specific design makes the heat exchanger more efficient the slower the chemical reactions in the catalyst are, and vice versa. Therefore, the catalytic device will, by itself, set itself for the right temperature so that all reactions precisely can be completed in the catalytic device.
